

# BASIC PROLOG

- Arithmetic using built-in operators
- Concatenating lists using *append* predicate
- Mapping example of transforming a list
- Reversing a List
- Syntax of data objects

# Arithmetic in Prolog

For efficiency uses built-in operators e.g.  $X$  is  $3 + 5$ ,  $>$ ,  $<$

**Example:**    `%factorial( N, F) :- F is the integer N factorial`  
                 `factorial( N, F) :- N > 0, N1 is N - 1,`  
                                 `factorial(N1, F1), F is N * F1.`  
                 `factorial( 0, 1).`

- cannot be used with 1st argument as variable

Iteration using Recursion      factorial/4 = 4 arguments

**Example:**    `factorial( N, F) :- factorial( 0, N, 1, F).`  
                 `factorial( I, N, T, F) :- I < N, I1 is I + 1,`  
                                 `T1 is T * I1, factorial( I1, N, T1, F).`  
                 `factorial( N, N, F, F).`

- computes :      `I is 0; T is 1;`  
                                 `WHILE I < N DO`  
   `I is I + 1; T is T * I      END;`  
                                 `RETURN T.`

- $I$  and  $T$  are values of loop vars before  $(I + 1)$ th iteration
- $I$  is loop counter and  $T$  the accumulator
- 4th arg of factorial/4 is instantiated to the solution

# Example Append with 3<sup>rd</sup> argument variable

**Example:**  $\text{append}([X|Xs], Ys, [X|Zs]) \leftarrow \text{append}(Xs, Ys, Zs).$   
 $\text{append}([], Ys, Ys).$

**Trace:**

$\text{append}(Xs, Ys, [a, b, c])$

$Xs = [a|Xs1]$

$\text{append}(Xs1, Ys, [b, c])$

$Xs1 = [b|Xs2]$

$\text{append}(Xs2, Ys, [c])$

$Xs2 = [c|Xs3]$

$\text{append}(Xs3, Ys, [])$

$Xs3 = [], Ys = []$

**TRUE**

**Output:**  $(Xs = [a,b,c], Ys = [])$

; (indicates forced backtrack)

$\text{append}(Xs2, Ys, [c])$

$Xs2 = [], Ys = [c]$

**TRUE**

**Output:**  $(Xs = [a,b], Ys = [c])$

;

$\text{append}(Xs1, Ys, [b,c])$

$Xs1 = [], Ys = [b,c]$

**TRUE**

**Output:**  $(Xs = [a], Ys = [b,c])$

;

$\text{append}(Xs, Ys, [a,b,c])$

$Xs = [], Ys = [a,b,c]$

**TRUE**

**Output:**  $(Xs = [], Ys = [a,b,c])$

;

**NO More Solutions**

new tail

Note if append clauses reversed,  
last solution would be first

## Example – mapping program

Example of a mapping program:

`%mapping( Xs, Ys) :- Ys is the result of applying a mapping to Xs`

`mapping( [X|Xs], [Y|Ys]) :-`

`map( X, Y), mapping( Xs, Ys).`

`mapping([ ], [ ]).`

`map('A', a).`

`map('B', b).`

`map('C', c).`

`map('D', d).`

Quotation ' ' indicates constant

? mapping(['B', 'D'], Z).

1<sup>st</sup> recursion Y=b

2<sup>nd</sup> recursion Y=d

## Example Reverse/2 = 2 arguments

```
%reverse( List, RevList) :- RevList is the result of reversing List
reverse( [ ], [ ] ).
reverse( [ X | Xs ], Zs ) :- reverse( Xs, Ys),
                             append( Ys,[ X ], Zs).
```

reverse([1],R) gives append([], [1],R)

reverse([2,1],R) gives append([1], [2],R)

reverse([3,2,1],R) gives append([1, 2], [3],R)

## Example Reverse/3 = 3 arguments

An extra argument can be used to build bottom-up:

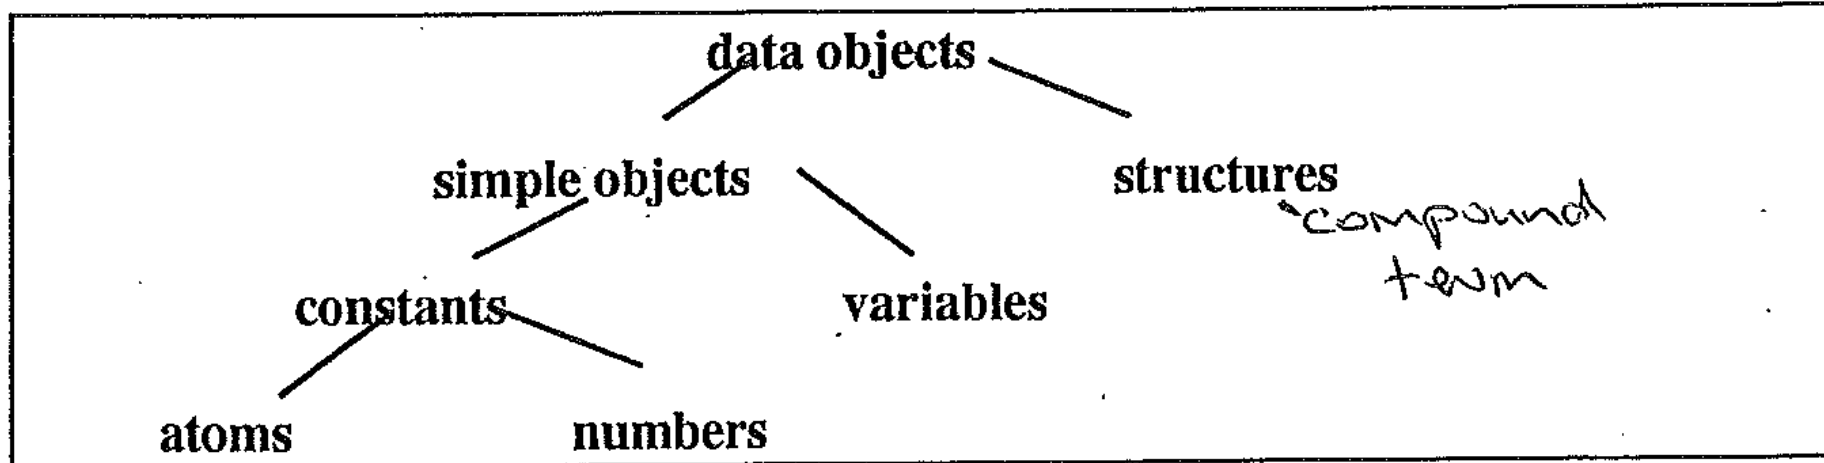

```
%reverse( List, Tsil) :- Tsil is the result of reversing List
reverse( Xs, Ys) :- reverse( Xs, [ ], Ys).
reverse( [X|Xs], Revs, Ys) :- reverse( Xs, [X|Revs], Ys).
reverse( [ ], Ys, Ys).
```

reverse/3 is introduced with 2nd arg as an accumulator

```
Trace:  reverse([a,b,c],Xs)
          reverse([a,b,c], [ ], Xs)
          reverse([b,c], [a], Xs)
          reverse([c], [b,a], Xs)
          reverse([ ], [c,b,a], Xs)
          Xs = [c,b,a]
          TRUE
```

Note that 3<sup>rd</sup> argument is carried through recursion, and instantiated to reversed list

# Data Object terminology

- **atoms** are strings of characters from upper-case, lower-case, digits, special chars and can be strings of:
  1. letters, digits and `_`, starting with lower-case
  2. special characters e.g. `+ - * / < > = & _`
  3. strings in single quotes
- **variables** are strings of upper-case, lower-case, digits, `_` starting with upper-case or `_`
  - a single `_` represents the anonymous variable.
